blinks == frontend
Actions == backend

Terminology

Solana Actions - are specification-compliant APIs that return transactions on the Solana blockchain to be previewed, signed, and sent to the network.

- QR codes
- Buttons + widgets
- Websites
- etc

Solana Actions

Deliver signable transactions
(and eventually messages)
to the user

- ❑ Public URLs on the internet
- ❑ Accept GET and POST requests
- ❑ Return metadata
- ❑ Return a signable transaction
 - ❑ This can do anything!
- ❑ Safety + Security
 - ❑ Actions come from domains (just like dApps)
 - ❑ Transactions are still simulated via wallets

Example Actions

- Voting on governance proposals
- Staking SOL
- Swapping digital assets
- Claiming digital collectibles
- Donating to support a creator, quadratic funding platform, or charity

Action Execution Lifecycle

**What are
blinks?**

blinks == frontend

Actions == backend

Terminology

Blockchain links – or **blinks** – turn any Solana Action into a shareable, metadata-rich link.

Blinks allow users to execute blockchain transactions directly from URLs, making decentralized applications accessible from any platform or device.

blinks are like embedded dApp widgets. sort of.

Blinks

client applications that introspect Action APIs and construct user interfaces around interacting with and executing Actions

- ❑ Client detects Actions and displays standardized UI
- ❑ Currently via browser extensions that inject this UI
- ❑ To be a blink:
 1. ``solana-action:` uri`
 2. `actions.json` file
 3. interstitial website using the ``action`` query parameter

`solana-action:` uri scheme

```
solana-action:https://actions.dialect.to/api/jupiter/swap/USDC-SOL
```

- No fallback website
- Least supported
- Least recommended

actions.json

- Map normal urls on your website to Action API endpoints
 - local relative links
 - external absolute links
 - wildcards are supported
- Allow anyone to share a normal link to your website, which will be converted to a blink
- Stored at the root of your domain
- Your website is the fallback UI

Example actions.json file

- Jupiter Swap website: <https://jup.ag/swap/USDC-SOL>
 - this is the link you share on social media and across the internet
- actions.json file at <https://jup.ag/actions.json>
- Maps (using wildcards):
 - ``/swap/USDC-SOL`` to
 - ``https://actions.dialect.to/api/jupiter/swap/USDC-SOL``

actions.json file

```
{
  "rules": [
    {
      "pathPattern": "/swap/**",
      "apiPath": "https://actions.dialect.to/api/jupiter/swap/**"
    },
    {
      "pathPattern": "/collection/*",
      "apiPath": "/api/actions/collection/*"
    }
  ]
}
```

- External absolute urls
- Internal relative urls
- Wildcards `*` and `**`

Interstitial website

- Uses `action` query parameter
 - Value of `solana-action:` uri
- Interstitial website is the fallback UI
- Standardized UI
- Allow you to build your Actions without building your own frontend UI and wallet connect flow

Interstitial website

```
https://dial.to/?action=solana-  
action:https://actions.dialect.to/api/jupiter/swap/USDC-SOL
```

- `action` query parameter
- value of the `solana-action:` uri scheme
- Interstitial is the fallback
- No need to build your own UI and wallet connect

How do Blinks unfurl/render?

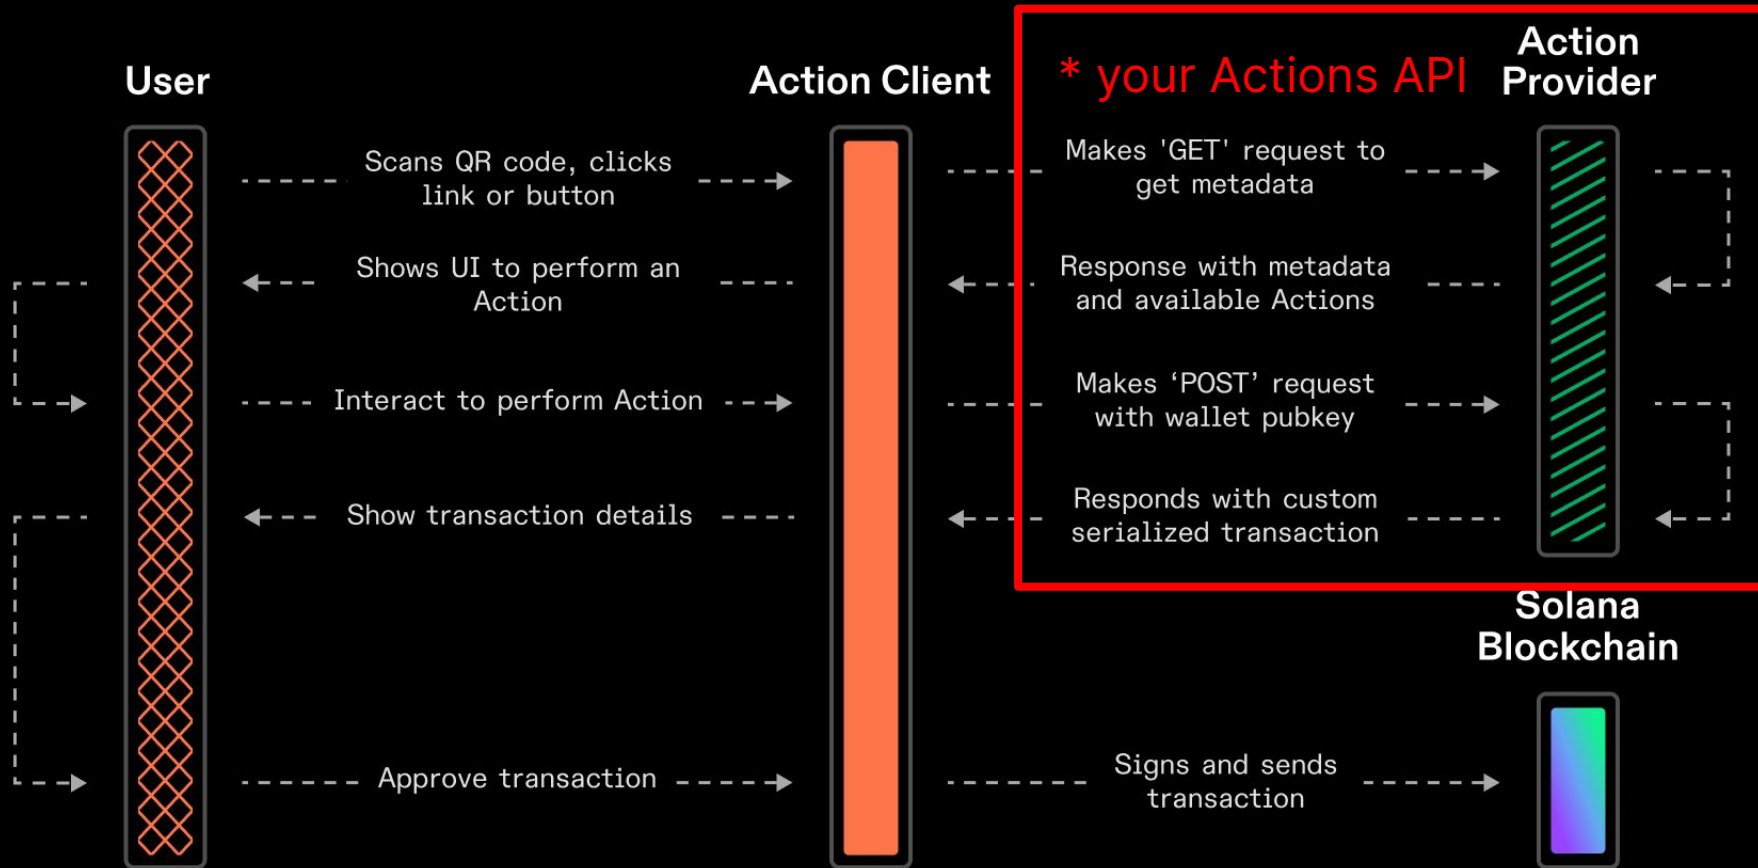

unfurl - unroll, unfold, or spread out or be unrolled, unfolded, or spread out from a furled state. “unfurl a banner”

- ❑ Blink client detects link on page
- ❑ Currently on X.com:
 1. Link must show social image
- ❑ Client checks:
 1. actions.json file or `action` query param
 2. Dialect's registry
 3. Fetch metadata
- ❑ If all checks pass ⇒
 - render blink
- ❑ If any check fails ⇒
 - everyone sees a regular link
 - (just like before)

**Let's get nerdy
about Actions**

Action Execution Lifecycle

GET Response

```
/**
 * Response body payload returned from the Action GET Request
 */
export interface ActionGetResponse {
  /** image url that represents the source of the action request */
  icon: string;
  /** describes the source of the action request */
  title: string;
  /** brief summary of the action to be performed */
  description: string;
  /** button text rendered to the user */
  label: string;
  /** UI state for the button being rendered to the user */
  disabled?: boolean;
  /** */
  links?: {
    /** list of related Actions a user could perform */
    actions: LinkedAction[];
  };
  /** non-fatal error message to be displayed to the user */
  error?: ActionError;
}
```

POST Request

```
/**
 * Response body payload sent via the Action POST Request
 */
export interface ActionPostRequest {
  /** base58-encoded public key of an account that may sign the
  transaction */
  account: string;
}
```

POST Response

```
/**
 * Response body payload returned from the Action POST Request
 */
export interface ActionPostResponse {
  /** base64 encoded serialized transaction */
  transaction: string;
  /** describes the nature of the transaction */
  message?: string;
}
```

Let's look at code!

<https://github.com/solana-developers/solana-actions/blob/6a34a8d99af87119d1ce71ab5321ebc90a531a69/examples/next-js/src/app/api/actions/transfer-sol/route.ts>

Solana Actions SDK

```
npm install @solana/actions
```
